

Hermes Turbo vs Baseline

Generated 2026-05-22 15:04 UTC • 500 iterations per stage • compares the runtime mechanisms added in the turbo fork (#81–#103 + P1–P7) against intentionally-naïve baselines.

Headline wins

129.68× router.DeterministicRouter.route	30.82× project_mapper.detect_fingerprint
--	--

Speedup per stage

Detailed results

Stage	p50 (μs)	p95 (μs)	Baseline (μs)	Speedup
project_mapper.detect_fingerprint	2895.4	3179.1	89232.0	30.82x
router.DeterministicRouter.route	1.4	1.5	186.6	129.68x
telemetry.receipts.content_hash	1.0	1.0	0.7	0.76x

Reading the numbers. Baselines are intentionally naïve (no validation, no disk, no contract enforcement). A speedup below 1× reflects the *cost of correctness* — the turbo path holds invariants the baseline ignores. Real wins live where the turbo path replaces an LLM call (router) or a full tree walk (project_mapper).
